Power-Up/Down Sequence

1. All the ASIC supplies must reach their respective nominal voltages within 20 ms of the start of the ramp-up sequence, though a shorter ramp-up duration is preferred. The maximum ramp-up rate is 20 mV/μs.
2. It is recommended that the 3.3-V rail ramp up first.
3. It is recommended that the 0.95-V rail reach at least 90% of its nominal value no later than 2 ms from the start of VDDC ramping up.
4. The power rails that are shared between the GPU and other components on the system should be ramped up first. The GPU should be ramped down (for example, AMD PowerXpress idle state), all the power rails are removed from the dGPU. The power rails that are shared between the GPU and other components must be 0 mV/μs.
5. VDDC and VDD_CT should not ramp up simultaneously. For example, VDDC should reach 90% before VDD_CT starts to ramp up (or vice versa).
6. For power down, reversing the ramp-up sequence is recommended.
